MORPHOLOGICAL ASYMMETRY ASSESSMENT

Objective: To evaluate if the patient has a morphological difference of the mandibular body or chin region between the right and left side that may give the patient an asymmetrical appearance. It's important to remember that sometimes the patient has not a size difference between the right and left sides (previous slide) but may have a morphological difference.

ARTICULAR FOSSA COMPENSATION ANALYSIS

Measures the right and left articular fossa in relation to the true axial plane.

Interpretation: To evaluate one of the regions where compensations of mandibular asymmetries are often present.

Observe if the patient has a size difference between the right and left side of the mandible and doesn't have mandibular deviation.

One of the areas where asymmetry may be compensated is at the height of the articular fossa.

FRONTAL ANGULATION OF THE MANDIBULAR RAMUS

FRONTAL/ ANTERIOR VIEW

POSTERIOR VIEW

Measures:

- Frontal Angle of the Right and Left Mandibular Ramus.
- Distance in mm from the condyle and the Gonion to the Median Sagittal Plane.

Interpretation: Both measurements allow us to observe differences in mandibular ramus angulation (torque) between the right and left sides. Differences between the sides can be showing another area of compensation of mandibular asymmetry (compensated asymmetry). *It is also important to note if there is a difference in the height of the gonial angles.

MORPHOLOGICAL AXIAL ANALYSIS

Right

Left

MEASURE: Distance in mm from the Condylion to the coronal plane.

Interpretation: Indicates differences in the anteroposterior position of the condyle and/or fossa, often being another of the compensatory regions of mandibular asymmetries.

TEMPOROMANDIBULAR JOINT ANALYSIS

SAGITTAL ANALYSIS – TEMPOROMANDIBULAR JOINT

CORONAL ANALYSIS – TEMPOROMANDIBULAR JOINT

TEMPOROMANDIBULAR JOINT ANALYSIS

EVALUATION OF CONDYLAR AXIAL SYMMETRY

AXIAL CONDYLAR ANGLE

Angle formed by the long axis of the condyle in axial view at the level of the central point of the condyle with the median sagittal plane. The literature has shown that very closed (acute $< 60^\circ$) or very horizontal ($> 80^\circ$) angles were observed more frequently in patients with disk displacement and condylar degenerative changes.

EVALUATION OF SKELETAL SYMMETRY TRIANGLES

Point A Triangle

Point B Triangle

EVALUATION OF SKELETAL SYMMETRY TRIANGLES

Difference Pog – PSM mm

On this slide we observe the degree of deviation of Pog with respect to PSM. It is important to observe if on slide 12 there is a difference between both sides and now no deviation is observed (<3.5 mm), we are in the presence of a compensated asymmetry.

EVALUATION OF SKELETAL SYMMETRY TRIANGLES

| SKELETAL CLASS | CLINICAL STANDARD |
|----------------|-------------------|
| Class I | 0,52 - 5,5 mm |
| Class II | > 5,5 mm |
| Class III | < 0,52 mm |

Linear difference – B-A mm

EVALUATION OF THE AMOUNT OF DISTALIZATION POSSIBLE IN THE MANDIBLE

4º QUADRANT - RIGHT SIDE

Measurement: shortest linear distances from the most lingual point of the distal root of the second molar to the inner border of the lingual cortex.
Interpretation: The distalization of the inferior molars is limited by the proximity of the distal root of the second molar to the lingual cortex and not by the distance from the crown of the second molar to the anterior border of the mandibular ramus.
